

A 12-week window. A river that has flooded **three times in five years.**

Everything here comes from your public record, not from inside knowledge. Villion packs and ships fast from one central packhouse, fed by units spread along the Hex River. When the river rises and the grid goes down, the risk is **not being able to see** the river, the pumps, the cold rooms or the people on the farms.

What we see in **your valley**

WHERE	WHAT HAPPENED IN MAY 2026 (VALLEY-WIDE)	WHAT IT COSTS
River and blocks	Third severe flood in five years; 100–120 ha affected in the Hex region; netting, trellis and irrigation lost	Up to R1.2m/ha to re-establish (SATI). Your exposure: to confirm
Pumps and water	River-side pumps and pipelines are the first assets the river reaches. Today, checking them usually means a drive.	Pump stations and downtime: to confirm
Power and cold chain	Eskom faults hit De Doorns and the surrounding farms; generators kept cold chains running	Sector: "millions of rands daily" on diesel (FreshPlaza, May 2026)
Roads and access	Roads and crossings washed away; some farms cut off; N1 closed for about four days	Unknown who and what is cut off until someone gets there
Harvest security	Stolen grapes are sold along the N1 in season (SAPS / Hex Valley Tourism)	Loss and food-safety risk: to confirm

The aim: when the river rises again, Villion sees it coming, knows what is running and who is safe, and keeps packing.

Your own **private backbone**, on a carrier-grade link

We bring a dedicated carrier link to your central packhouse at Werda. From there, Villion owns a private network that runs along the valley to each Hex unit and to Nuy. Its relays sit on high ground with their own solar and battery power, so the network stays up when the grid does not. River levels, pumps, cold rooms, generators, cameras and voice all run on that one backbone. CTTX supports it under SLA.

Early warning, not hindsight

River-level and rain sensors upstream and at your farms send alerts to managers' phones. That gives you time to shut down or lift pumps, move equipment and close crossings before the water arrives, and to make sure the people living near the river are safe.

Pumps and water without the drive

Pump state, pressure, flow and power are visible from the office. Faults show up as they happen, not on the next round, and water use is on record.

A cold chain you can prove

Cold-room temperatures, generator run-hours and fuel levels stay visible through a grid outage. You get the temperature record your buyers ask for, and diesel you can manage.

Owned, not rented

The network is built into the rebuild and belongs to Villion. It is not a separate service at each unit that has to be replaced after every flood. CTTX supports it under SLA.

Proof that fits: Sandy Mountain, a 33,000 ha off-grid reserve

The reserve went from a 3/8 Mbps consumer service to 100 Mbps symmetrical carrier backhaul. It now has an 800+ Mbps backbone across the property on off-grid solar relays with battery telemetry, and call-outs have dropped to zero.

Next step

- 1 A 20-minute conversation.** What did you lose sight of on 11–12 May, and what is being rebuilt now?
- 2 A desktop terrain and line-of-sight review of your Hex units and Nuy.** This is the first step in designing Villion's own network, completed before anyone drives out.
